*World's Finest MIM Technology from Japan "\mu-MIM®* 

Volume 21

## in walled

## 1. Leave the thin-walled components to µ-MIM

In any processing, manufacturing of thin-walled components including maintaining the accuracy is quite difficult since these are easilv affected thermally or mechanically. However, from the miniaturization and weight saving point of view, the thin-walled components are required in every industry. In conventional MIM is also difficult to manufacture the thin film components since injection or removing from the mould is required technique and experiences. Additionally, during the degreasing serious and sintering process, deformation will be observed even if it was successful in injection or forming of thin-walled components. However, Taisei Kogyo has studied and developed to apply our µ-MIM the technology to thin-walled components and successfully mass produce less than 100 µm wall The thin-walled component. components or minuteness shape mass production will be realised by our µ-MIM processing technology.

## 2. Break-through in raw material pellets

Below SEM image is our µ-MIM product. We have realised a structure of 5 µm morphology. It is impossible to process by the conventional MIM, or few years ago for even our  $\mu$ -MIM since there was limitation of purchasing the fine metal powder. Though today our µ-MIM has been realised the single micron order morphology. In general MIM, it is applied the diameter of few dozen microns metal powder, and it is not able to realise less than 500µm structure. However, we employ the latest fine powders and also classify the diameter to achieve less than 10 µm morphology.

This achievement is because of our binder system, which developing by ourselves.

## SEM images 3. Break-through in mould and forming technologies

It is difficult to manufacture stably even the products with 0.5 mm thickness part by the general MIM technology. One of the reasons is the rheological characterization of the raw materials (Feedstock). The MIM feedstock has lower fluidity comparing with the resin feedstock for plastic injection moulding due to the metal powder. Moreover, the metal powder thermal has high conductivity. Thus, in the cool mould the feedstock temperature is decreased faster and this will the fluidity even lower. help Therefore, it is required high mould design technology and lots of injection knowhow in MIM production. Taisei Kogyo applied the various knowhow and mould design simulation to realise thin-wall components mass production. We recently realise a component which pipe has various flow passages, thickness of 0.2 mm or less at whole part as shown in below figure.

## 4. Process change of soft magnetic materials

**Materials** which have weak power retaining magnetic and have high permeability are called soft magnetic materials. Soft magnetic material is strongly magnetized under magnetic field only, and it is used in various

## Issued date: : 28 Feb 2018

industries as the functional materials with additional value.

Recently, it is used more in various purposes and industries such as pneumatic-hydraulic equipment, solenoid valves for fuel injection unit of automobile, solenoid core, injector core, plunger, torque sensor core, etc. Generally the soft magnetic parts are manufactured machining by or powder metallurgy. Therefore, it is limited to mass produce the soft magnetic components required high accuracy or microstructure morphology, Taisei Kogyo has developed MIM production the soft magnetic parts supported by ministry of economy, trade and industry, Japan. Our developed technology will realise the mass production of small complicated design, integration of magnetic and non-magnetic material in a magnetostrictive part without stress.

## Taisei Column

Hello Everyone. My name is Vergne Marcelo and I come from Brazil. I joined Taisei Kogyo in May 2017 so I am still new.

I work as an engineer in the quality assurance department. Taisei Kogyo with its micro-MIM technology is a workplace which makes me an effort to do my best everyday and there are always new challenaes. My speciality is simulation/analysis and programming, however, it is not easy to analyse new composite materials or micro parts that are very complicated. And I gain new experiences through these work. My hobby is travelling and Capoeira (an Afro-Brazilian martial art). I studied in Canada for 2 years and now I live in Japan since 2016. I play Capoiera almost every week with my friends. Capoiera is a good sports where you can enjoy dance, music and acrobatics. If you are interested in MIM, studying abroad, travelling or Capoeira, let's be friends!
